Template for pandoc / markdown manuscripts	1
Timothée Poisot <sup>1,2</sup> and Second Author <sup>2,3</sup>	2
<sup>1</sup> Université de Montréal, Département de Sciences Biologiques <sup>2</sup> Québec Centre for Biodiversity Sciences <sup>3</sup> University of Whatever	3 4 5
February 9, 2018	6
This template uses the magic of makefiles, pandoc, and markdown, to make it easy to produce multiple documents from markdown, R markdown, or Julia markdown files. Just type make at the command line to see the different options.	7 8 9
Keywords: ecological networks - beta-diversity - biogeography	10
Correspondence to Timothée Poisot — timothee.poisot@umontreal.ca	11

This project intends to make the generation of high-quality preprints from markdown, R markdown, and Julia markdown documents easy. Once downloaded, type make to see the output. This will generate two pdf documents and one OpenDocument file.

13

14

16

17

21

25

29

1 Installation

To get started, you will need the python pandoc-fignos, pandoc-eqnos, and pandoc-tablenos filters.

l make dependencies

Make sure that pandoc and pandoc-citeproc are installed, and that you have a LaTeX installation. You will also need an installation of node. If you want to use this template with reproducible documents, you will need either knitr or Weave.jl.

## 2 Document options

There are two important files to edit to specificy the manuscript informations. First, authors.yaml should be self-explanatory; it contains the author names, email address for the corresponding author, and affiliations. The infos.yaml file is for the manuscript title, keywords, etc. Finally, the ABSTRACT file has the abstract. It can contain markdown formatting.

2.1 Tables 26

Table legends go on the line after the table itself. To generate a reference to the table, use {#tbl:id} – then, in the text, you can use {@tbl:id} to refer to the table. For example, the table below is table 1. You can remove the *table* in front by using !@tbl:id, or force it to be capitalized with \\*tbl:id.

**Table 1** This is a table, and its identifier is id – we can refer to it using {@tbl:id}. Note that even if the table legend is written below the table itself, it will appear on top in the compiled document.

Using	produces
<pre>@tbl:id</pre>	table 1
!@tbl:id	1
\*@tbl:id	Table 1

## 2.2 Equations

Equations can be referenced using the same syntax as tables, using the eq prefix in place of tb1. For example:

$$y = mx + b \tag{1}$$

30

31

32

33

35

36

37

38

42

We can refer to eq. 1 in the text.

## 2.3 Adding references

References go in the references.json file, at the root of the project. References are cited with @key, where key is the unique identifier of the reference. Both inline, like Hutchinson (1959), and in brackets (Hutchinson 1957) can be used.

You can also have footnotes.<sup>1</sup>

# 2.4 Figures

Figures can be used with the usual markdown syntax. After the path, you can use {#fig:id width=50%} to specify
the width and the reference. See table 1 for how to cite. The code below in the markdown source produces fig. 1.

[Figure 1 about here.]

#### 3 Other elements

3.1 Code blocks

You can use fenced code blocks to render code:

```
1 // Update affiliations
2 var print_affiliations = []
3 for (var af in affiliations) {
4  var afobject = {}
5  afobject.id = affiliations[af]
45
46
47
48
```

<sup>&</sup>lt;sup>1</sup>this is a footnote – it is actually rendered as a sidenote in the preprint format.

```
6
      afobject.text = af
                                                                                                                       50
7
      print_affiliations.push(afobject)
                                                                                                                       51
  }
8
                                                                                                                       52
   Note that code blocks have line numbers of the left, so this does not interfer with the line numbers of the text (which
   are on the right).
                                                                                                                       54
         Track changes
                                                                                                                       55
   You can use make diff to create a marked-up pdf document. The git revision can be specified with the TAG variable
   of make (by default, the latest commit). The other option is AS, which can be draft or preprint, to render the
   marked-up version as a draft or as a preprint.
                                                                                                                       58
        Editorial marks
   3.3
   Critic Markup is rendered:
                                                                                                                       60
   Don't go around sayingto people that the world owes you a living. The world owes you nothing. It was here first.
   One Only one thing is impossible for God: To find any sense in any copyright law on the planet. Truth is stranger than
   fiction[strange but true], but it is because Fiction is obliged to stick to possibilities; Truth isn't.
                                                                                                                       63
   Note that CriticMarkup is not rendered into OpenDocument.
                                                                                                                       64
         Using with knitr, Weave.jl, ...
   3.4
                                                                                                                       65
   Just type make. If there is a Rmd or Jmd document with the same base name, the makefile will render the markdown
   document for you.
                                                                                                                       67
   Note that the extensions must be Rmd or Jmd, with an uppercase first letter. Of course you will need knitr (for R) or
   Weave.jl (for julia).
                                                                                                                       69
   Because of the way figures are refered to (using the Ofig:id syntax), it is better to generate the figure first, and then
                                                                                                                       70
   call it in the text, using fig.show='hide'. The code below will generate fig. 2.
                                                                                                                       71
   plot(sort(rnorm(200)), type='1')
                                                                                                                       72
   You can then use this figure:
```

77

85

With knitr, the kable function can create tables. If you add the caption paragraph immediately below, then these tables can be cited. This is how we produce table 2.

**Table 2** This is a table, and its identifier is knit – we can refer to it using {@tbl:knit}. Note that even if the table legend is written below the table itself, it will appear on top in the compiled document.

Sepal.Length	Sepal.Width	Petal.Length	Petal.Width	Species
5.1	3.5	1.4	0.2	setosa
5.0	3.6	1.4	0.2	setosa
5.4	3.9	1.7	0.4	setosa

## 4 Text example

We posit that four simple rules govern the evolution of networks. First, every network originally consists of just two species sharing a single interaction; for example, a plant and its herbivore. Second, a speciation event happens at the top level (e.g.) the herbivore) with probability p, or at the bottom level with probability 1-p. Third, the incipient species starts with all interactions of its ancestor. Fourth, some of these interactions are lost with probability  $\varepsilon(\lambda, k, c)$ , which allows interactions—that are gained through speciation—to be lost either at a fixed rate  $\lambda$  or as a function of the incipient species' degree k. The c parameter modulates this relationship further by influencing whether high degree of an ancestor increases, or decreases, the probability of the incipient species losing interactions. We have used the following formulation for  $\varepsilon$ :

$$\varepsilon(\lambda, k, c) = \left(1 + \left(\frac{1}{\lambda} - 1\right) \times c^{k-1}\right)^{-1}.$$
 (2)

In this formulation, k is the number of interactions of the incipient species,  $\lambda$  is the *basal* rate of interaction loss, and c is a parameter regulating whether species with more interactions tend to gain or lose interactions over time. Negative values of c imply that rich get richer, i.e. species with more interactions tend to conserve them more over speciation. The special case of c = 0 corresponds to no relationship between the degree of a species and its probability of losing or retaining an interaction over speciation. The resulting probability of interaction loss, and its consequences on degree, is shown in figure. The values of  $\epsilon$  belong to ]0;1[. Note that, because species are

duplicated upon a speciation event, the network still grows over time. If an incipient species should lose all of its interactions, then it fails to establish.

These four rules translate directly into steps for the model: pick a level at random, select a species to duplicate, assess the survival of interactions of the incipient, and add the incipient to the network. These are performed a fixed number of time – we impose an upper limit to the richness at each level, and when this limit is reached, the incipient species replaces one of the resident species at random. An equilibrium for the measures of network structure (see next section) is reached within 1000 timesteps. For all situations, we recorded the network after 5000 iterations.

**Network measures** 

4.1.1 Connectance 100

Connectance, defined as the ratio of realized interactions on the total number of potential interactions, is one of the most common descriptor of network structure. In a bipartite network with T species at the top, and B at the bottom, having a total of L interactions, it is defined as  $Co = L/(T \times B)$ . Connectance has a lower bound, as the network 103 cannot have fewer interactions that the number of species in its more speciose level – the minimal connectance is 104 therefore  $c_m = \max(T, B)$ . This makes the connectance of networks of different sizes difficult to compare, especially since bipartite networks tends to have a low connectance. For this reason, we used a corrected version of connectance, defined as

$$Co^{\star} = \frac{L - c_m}{T \times B - c_m} \,. \tag{3}$$

93

107

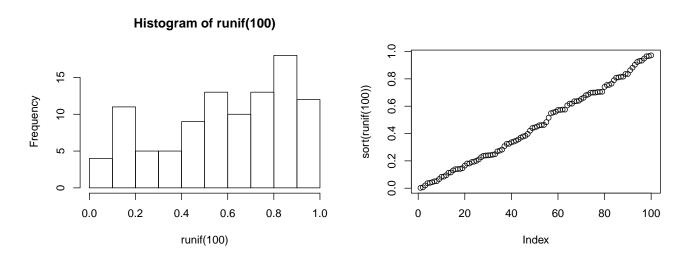

This takes values between 0 (the network has the minimal number of interactions) and 1 (all species are connected), but is robust to variations in species richness. 109
